Analyze the provided dataset to identify its key characteristics for data-driven decision-making. Upon receiving a specific analytical question, address it strictly using the dataset. Your deliverables must include a clear, concise answer to the question and the Python code that extracts and processes the data used to derive your answer.

I've received your dataset. I'll first inspect its structure to understand its contents. Then, you can provide a specific analytical question for me to address. Let me check the file now.

The dataset contains **167,826 rows and 9 columns**. Key columns include:

- **Country/Region:** Name of the country or region.
- **UNICEF_Region:** Associated UNICEF region.
- **Indicator:** Type of HIV-related metric (e.g., incidence rate, prevalence).
- **Year:** Year of data.
- **Sex:** Gender category (Both, Male, Female).
- **Age:** Age group (e.g., 0-14, 15-19).
- **Value:** Reported data value.
- **Lower/Upper:** Confidence intervals for estimates.

Some values in the dataset appear to be non-numeric (e.g., "<0.01"), which may require cleaning for numerical analysis.

What specific question would you like me to analyze? [?]

What is the mean annual incidence of new HIV cases globally between 2005 and 2023?

To calculate the **mean annual incidence of new HIV cases globally** between 2005 and 2023, I will:

1. **Filter** the dataset for the indicator related to new HIV infections.
2. **Convert** the "Value" column to numeric, handling cases where values are represented as strings (e.g., "<0.01").
3. **Group** by year and compute the mean annual incidence.

Let's process the data now.

The **mean annual incidence of new HIV cases globally** has been **declining** from **1.81 per 100,000 people** in 2005 to **0.41 per 100,000 people** in 2023.

Here is the Python code used to compute these values:

```
python
# Filter for incidence-related indicators
incidence_df = df[df["Indicator"].str.contains("incidence", case=False, na=False)]

# Convert "Value" column to numeric, replacing non-numeric values
incidence_df["Value"] = pd.to_numeric(incidence_df["Value"], errors="coerce")

# Filter data between 2005 and 2023
incidence_df = incidence_df[(incidence_df["Year"] >= 2005) & (incidence_df["Year"] <= 2023)]

# Compute the mean annual incidence
mean_annual_incidence = incidence_df.groupby("Year")["Value"].mean()
```

Would you like a visualization of this trend? [?]
